24X7 Call Center # [7353-040-000](tel:7353-040-000)

A 45-year-old man presented with recent onset stridor. Four months earlier, he had had a neck abscess which was drained and required intubation, mechanical ventilation and tracheostomy tube placement. As the general condition of the patient improved, he was decannulated 10 days after the initial tracheostomy. The patient slowly developed a breathy voice which progressed to stridor.

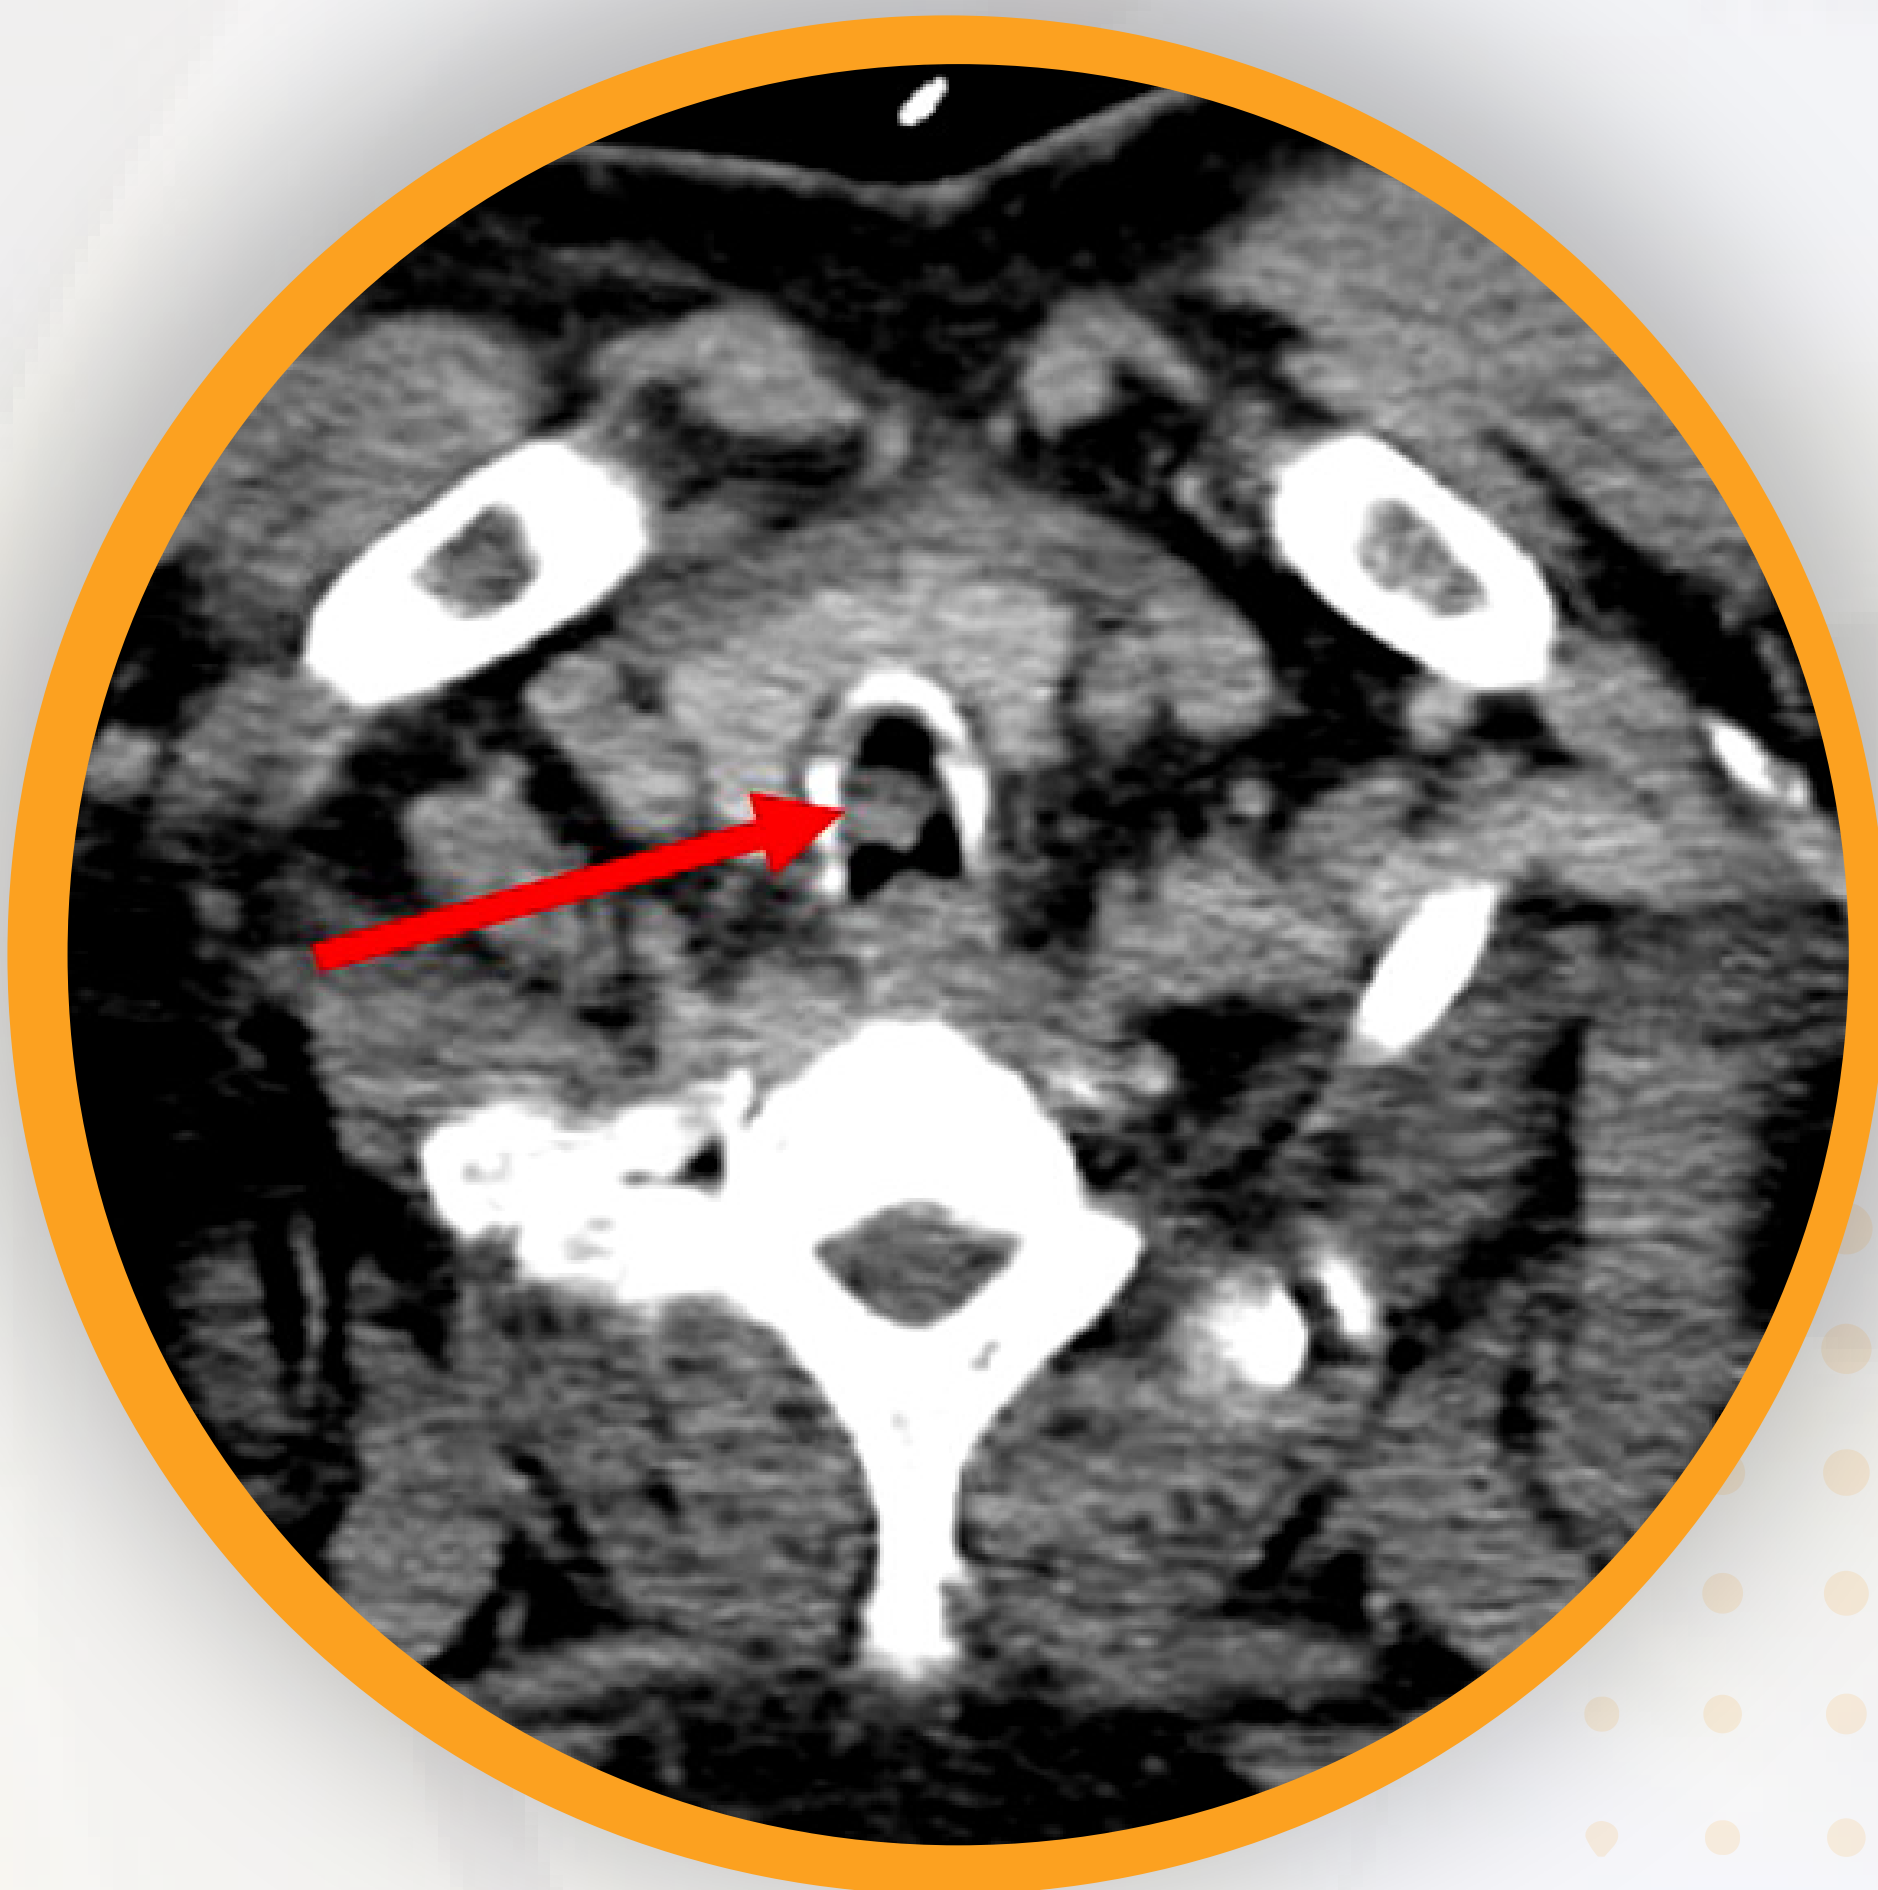

Fig. No 1: CT scanning of the neck showed an endotracheal mass at 1st tracheal ring.

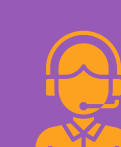

Fig. No 2: Bronchoscopy revealed a endotracheal mass.

Flexible bronchoscopy revealed a large spherical mass that obstructed the tracheal lumen.

It was excised with TRANSORAL CO2 LASER MICROSURGERY. Histopathology revealed granulation tissue and chronic inflammation. A repeat bronchoscopy was performed 4 months later and did not show any residual abnormality.

A high index of suspicion of post-tracheotomy granulation tissue should be considered in the differential diagnosis of airway obstruction due tracheostomy tube placement. TRANSORAL CO2 LASER MICROSURGERY is an effective treatment modality in such a situation.
